Introduction

Electromagnetic waves produced by radio-frequency (RF) transmitters (e.g. radio, television and radar) will induce electric currents and voltages in any firing circuit including leading wires of the electroexplosive device (EED) on which they impinge. The magnitude of the induced current and voltages depends upon the configuration of the firing circuit and leading wires relative to the wavelength of the transmitted signal and on the strength of the electromagnetic field. If the induced current which is transferred to the EED is in excess of the no fire current then the EED could initiate. This European Technical Report provides a systematic approach to assist transmitter operators, quarry managers and all others concerned with a logical method for the assessment and elimination of the initiation of EED by RF. can b.
rs of vario. The assessment procedures contained in this European Technical Report are based on measurements of the powers and current that can be extracted from typical firing circuits and leading wires and on the physical electrical parameters of various types of EED.

1 Scope

This European Technical Report provides guidance on assessing the possibility of inadvertent extraction of energy from an electromagnetic field propagated from radio frequency (RF), radar or other transmitter antennas and the coupling of this energy to an electro-explosive device (EED) in a manner capable of causing initiation. The frequency range covered by this European Technical Report is 9 kHz to 60 GHz. This European Technical Report only applies to bridge-wire devices which are directly initiated by radio frequency current and does not apply to special detonators, for example, electronic detonators. It does not cover the similar hazard arising from electromagnetic fields generated by other means, for example electric storms, electricity generating plant or power transmission lines.

This European Technical Report does not apply to the following equipment:

- air bag igniters for automotive applications (including the igniters before they are fitted);
- special pyrotechnic devices;
- pyromechanisms;
- igniters for fireworks;
- special military devices;
- special safety equipment.

NOTE The methods of assessment from 9 GHz to 60 GHz are based on extrapolation of data for frequencies below 9 GHz.

2 Normative references

No normative references are made in this standard.

3 Terms and definitions

For the purposes of this European Technical Report the following terms and definitions apply.

3.1

duty cycle

product of pulse duration (in seconds) and the pulse repetition frequency (in pulses per second)

3.2

electro-explosive device (EED)

one shot explosive or pyrotechnic device initiated by the application of electrical energy

NOTE EED is used to refer to either a single electro-explosive device or several devices, to comply with general practice within the industry.

3.3

hazard

potential source of danger to life, limb or health, or of discomfort to a person or persons, or of damage to property

3.4

safe distance

distance outside which it is considered that there is no potential hazard
